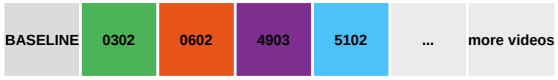
From continuous movement to emotion-specific micromovement signatures

Workflow summary: segment trials, isolate the low-speed regime, pool samples by emotion, compare distributions, and map the strongest pairwise differences back onto the body.

1. Record a continuous session

One long mocap recording is later segmented into baseline and stimulus windows.

Continuous Vicon trajectory data

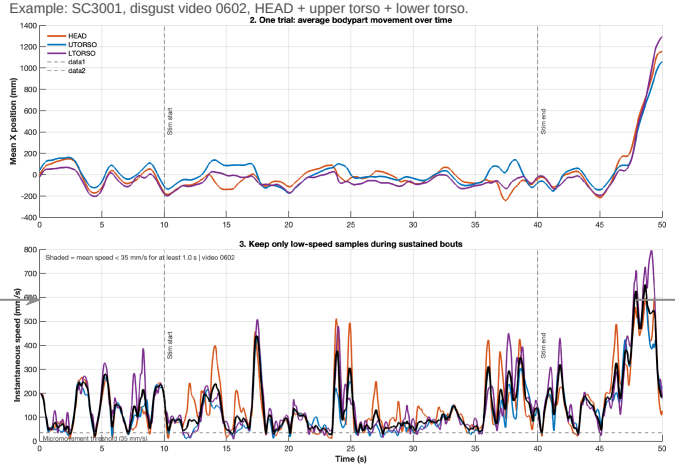


Each block becomes one trial window aligned to the Unity log schedule.

Inter-report intervals are not used in the current emotion analysis.

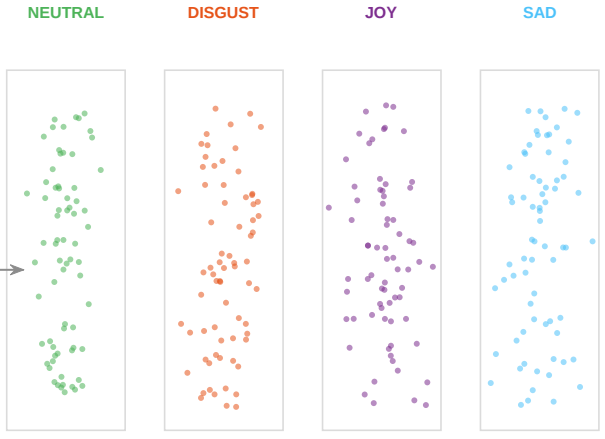
2. Isolate the micromovement regime

Example: SC3001, disgust video 0602, HEAD + upper torso + lower torso.



3. Pool low-speed samples by emotion

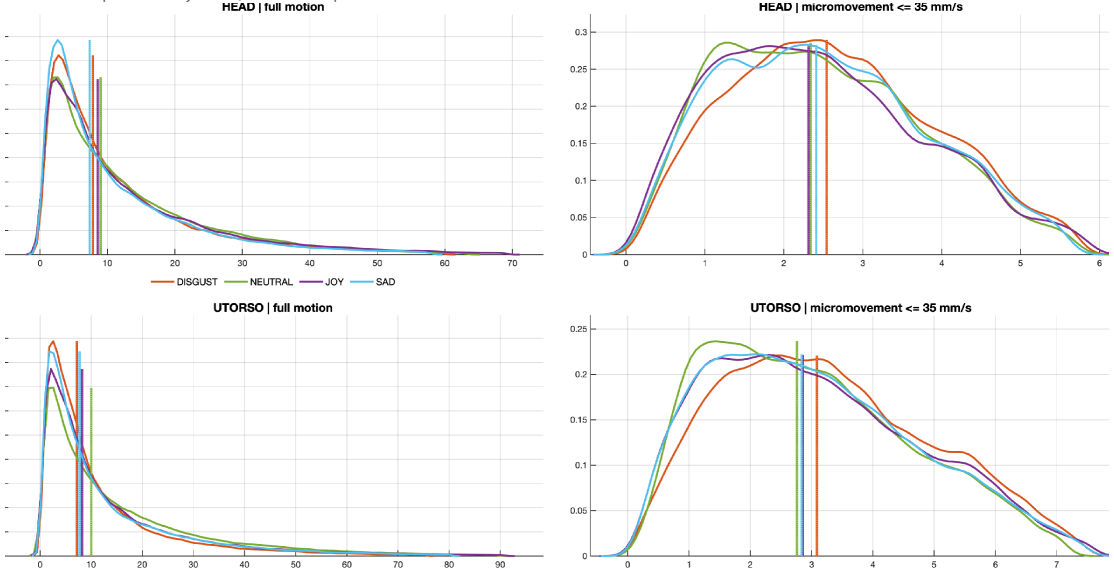
All low-speed samples from the selected bodypart are accumulated across trials and subjects.

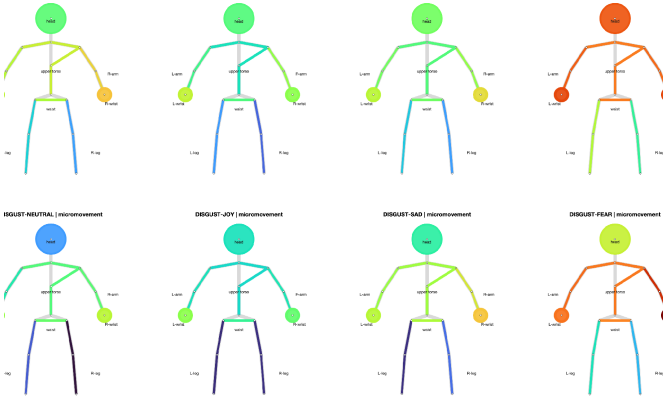


Each bodypart/emotion pool contains many low-speed samples collected across trials and subjects.

4. Compare the resulting distributions

Here shown as pooled density curves; the same samples can also be summarized as CDFs.



5. Map pairwise emotion differences onto the body


Unsigned KS intensity asks where a given emotion pair differs most strongly.
